SPECIFICATION

MANUFACTURING METHOD OF GAS SENSOR AND MANUFACTURING MACHINE THEREFOR

BACKGROUND OF THE INVENTION

1 Technical Field of the Invention

5 The present invention relates generally to a manufacturing method of a gas sensor which may be used in air-fuel ratio control of automotive internal combustion engines and a manufacturing machine therefore, and more particularly to a manufacturing method and machine for such a gas sensor which is capable of
10 establishing a hermetic seal in the gas sensor reliably.

2 Background Art

 Japanese Patent Publication No. 2847418 discloses a typical gas sensor used to measure an oxygen content of exhaust gasses of an automotive internal combustion engine. In this sensor, a cup or
15 cover is joined to a sensor holder by staking, therefore, a sufficient degree of sealing between a sensor element and the atmosphere, i.e., the outside of the cover is not obtained.

SUMMARY OF THE INVENTION

 It is therefore an object of the invention to provide an
20 improved manufacturing system for a gas sensor which is capable of establishing a required hermetic seal in the gas sensor.

 According to the first aspect of the invention, there is provided a gas sensor manufacturing method which comprise the steps of: (1) preparing an assembly which has a length and includes
25 (a) a housing which has a length made up of a first end portion, a

0950736-0947

second end portion, and a flange between the first and second end portions, (b) a cover which is made up of a small-diameter portion, a large-diameter portion, and a shoulder formed between the small-diameter portion and the large-diameter portion, (c) a first insulation porcelain disposed in the large-diameter portion of the cover in contact with the shoulder through an elastic member, (d) a second insulation porcelain disposed in the housing in contact of an end thereof with an end of the first insulation porcelain in alignment with each other, and (e) a laminated sensor element disposed in the second insulation porcelain; (2) pressing the cover against the housing in a lengthwise direction of the assembly to fit an end of the large-diameter portion of the cover on the first end portion of the housing to form an overlap; (3) tacking the large-diameter portion of the cover to the first end portion of the housing at the overlap while pressing the cover against the housing; (4) rotating the assembly about the length thereof; and (5) welding the large-diameter portion of the cover to the first end portion of the housing over the overlap.

In the preferred mode of the invention, the pressing steps presses the cover against the housing while compressing the elastic member to urge the second insulation porcelain against an inner wall of the housing elastically to establish a hermetic seal between an outer wall of the second insulation porcelain and the inner wall of the housing.

The welding step is performed while pressing the cover against the housing.

The pressure exerted on the cover may alternatively be

released after the tacking step.

The welding step is performed by laser welding.

The tacking step makes at least two tack welds in the overlap of the cover and the housing.

5 According to the second aspect of the invention, there is provided a gas sensor manufacturing method which comprises the steps of: (1) preparing an assembly which has a length and includes (a) a housing which has a length made up of a first end portion, a second end portion, and a flange between the first and second end
10 portions, (b) a cover which is made up of a small-diameter portion, a large-diameter portion, and a shoulder formed between the small-diameter portion and the large-diameter portion, and (c) an insulation porcelain disposed in the large-diameter portion of the cover in contact with the shoulder through an elastic member, (d) a
15 cup-shaped sensor element disposed in the housing; (2) pressing the cover against the housing in a lengthwise direction of the assembly to fit an end of the large-diameter portion of the cover on the first end portion of the housing to form an overlap; (3) tacking the large-diameter portion of the cover to the first end portion of the
20 housing at the overlap while pressing the cover against the housing; (4) rotating the assembly about the length thereof; and (5) welding the large-diameter portion of the cover to the first end portion of the housing over the overlap.

 In the preferred mode of the invention, the pressing steps
25 presses the cover against the housing while compressing the elastic member to urge the sensor element against an inner wall of the

housing elastically to establish a hermetic seal between an outer wall of the sensor element and the inner wall of the housing.

The welding step is performed while pressing the cover against the housing.

- 5 The pressure exerted on the cover may alternatively be released after the tacking step.

The welding step is performed by laser welding.

The tacking step makes at least two tack welds in the overlap of the cover and the housing.

- 10 According to the third aspect of the invention, there is provided a gas sensor manufacturing method which comprises the steps of: (1) preparing an assembly which has a length and includes (a) a housing which has a length made up of a first end portion, a second end portion, and a flange between the first and second end
- 15 portions, (b) a cover which is made up of a small-diameter portion, a large-diameter portion, and a shoulder formed between the small-diameter portion and the large-diameter portion, (c) a first insulation porcelain disposed in the large-diameter portion of the cover in contact with the shoulder through an elastic member, (d) a
- 20 second insulation porcelain disposed in the housing in contact of an end thereof with an end of the first insulation porcelain in alignment with each other, and (e) a laminated sensor element disposed in the second insulation porcelain; (2) pressing the cover against the housing in a lengthwise direction of the assembly to fit an end of the
- 25 large-diameter portion of the cover on the first end portion of the housing to form an overlap; and (3) welding the large-diameter

09960736-092404
T04269-9C/09650

portion of the cover to the first end portion of the housing at the overlap while pressing the cover against the housing.

In the preferred mode of the invention, the pressing steps presses the cover against the housing while compressing the elastic member to urge the second insulation porcelain against an inner wall of the housing elastically to establish a hermetic seal between an outer wall of the second insulation porcelain and the inner wall of the housing.

The welding step is performed while rotating the cover and the housing.

The welding step may alternatively be performed while fixing the cover and the housing.

The welding step welds the large-diameter portion of the cover to the first end portion of the housing around an overall periphery of the overlap through laser welding.

According to the fourth aspect of the invention, there is provided a gas sensor manufacturing method which comprises the steps of: (1) preparing an assembly which has a length and includes (a) a housing which has a length made up of a first end portion, a second end portion, and a flange between the first and second end portions, (b) a cover which is made up of a small-diameter portion, a large-diameter portion, and a shoulder formed between the small-diameter portion and the large-diameter portion, and (c) an insulation porcelain disposed in the large-diameter portion of the cover in contact with the shoulder through an elastic member, (d) a cup-shaped sensor element disposed in the housing; (2) pressing the

cover against the housing in a lengthwise direction of the assembly to fit an end of the large-diameter portion of the cover on the first end portion of the housing to form an overlap; and (3) welding the large-diameter portion of the cover to the first end portion of the housing at the overlap while pressing the cover against the housing.

In the preferred mode of the invention, the welding step is performed while rotating the cover and the housing.

The welding step may alternatively be performed while fixing the cover and the housing.

The welding step welds the large-diameter portion of the cover to the first end portion of the housing around an overall periphery of the overlap through laser welding.

According to the fifth aspect of the invention, there is provided a gas sensor manufacturing method which comprise the steps of: (1) preparing an assembly which has a length and includes (a) a housing which has a length made up of a first end portion, a second end portion, and a flange between the first and second end portions, (b) a cover which is made up of a small-diameter portion, a large-diameter portion, and a shoulder formed between the small-diameter portion and the large-diameter portion, (c) a first insulation porcelain disposed in the large-diameter portion of the cover in contact with the shoulder through an elastic member, (d) a second insulation porcelain disposed in the housing in contact of an end thereof with an end of the first insulation porcelain in alignment with each other, and (e) a laminated sensor element disposed in the second insulation porcelain; (2) pressing the cover against the

housing in a lengthwise direction of the assembly until a pressure exerted on the housing reaches a given pressure level to fit an end of the large-diameter portion of the cover on the first end portion of the housing to form an overlap; and (3) welding the large-diameter
5 portion of the cover to the first end portion of the housing at the overlap while pressing the cover against the housing.

In the preferred mode of the invention, the pressing steps presses the cover against the housing while compressing the elastic member to urge the second insulation porcelain against an inner
10 wall of the housing elastically to establish a hermetic seal between an outer wall of the second insulation porcelain and the inner wall of the housing.

The given pressure level is 1.2 times greater than or equal to an elastic pressure produced by the elastic member.

15 According to the sixth aspect of the invention, there is provided a manufacturing method which comprise the steps of: (1) preparing an assembly which has a length and includes (a) a housing which has a length made up of a first end portion, a second end portion, and a flange between the first and second end portions,
20 (b) a cover which is made up of a small-diameter portion, a large-diameter portion, and a shoulder formed between the small-diameter portion and the large-diameter portion, and (c) an insulation porcelain disposed in the large-diameter portion of the cover in contact with the shoulder through an elastic member, (d) a
25 cup-shaped sensor element disposed in the housing; (2) pressing the cover against the housing in a lengthwise direction of the assembly

09960736-092404
T04250-9529560

until a pressure exerted on the housing reaches a given pressure level to fit an end of the large-diameter portion of the cover on the first end portion of the housing to form an overlap; and (3) welding the large-diameter portion of the cover to the first end portion of the housing at the overlap while pressing the cover against the housing.

In the preferred mode of the invention, the pressing steps presses the cover against the housing while compressing the elastic member to urge the sensor element against an inner wall of the housing elastically to establish a hermetic seal between an outer wall of the sensor element and the inner wall of the housing.

The given pressure level is 1.2 times greater than or equal to an elastic pressure produced by the elastic member.

According to the seventh aspect of the invention, there is provided a gas sensor manufacturing machine designed to produce a gas sensor using an assembly which has a length and includes (a) a housing which has a length made up of a first end portion, a second end portion, and a flange between the first and second end portions, (b) a cover which is made up of a small-diameter portion, a large-diameter portion, and a shoulder formed between the small-diameter portion and the large-diameter portion, (c) a first insulation porcelain disposed in the large-diameter portion of the cover in contact with the shoulder through an elastic member, (d) a second insulation porcelain disposed in the housing in contact of an end thereof with an end of the first insulation porcelain in alignment with each other, and (e) a laminated sensor element disposed in the second insulation porcelain. The machine comprises: (1) a first

annular press plate fitted on the first end portion of the housing in engagement with the flange; (2) a second annular press plate fitted on the small-diameter portion of the cover in engagement with the shoulder of the cover; and (3) a pressing means for pressing the cover against the housing in a lengthwise direction of the assembly to fit an end of the large-diameter portion of the cover on the first end portion of the housing to form an overlap; (4) a tacking means for tacking the large-diameter portion of the cover to the first end portion of the housing at the overlap while pressing the cover against the housing; (5) a rotating means for rotating the assembly; and (6) a welding means for welding the large-diameter portion of the cover to the first end portion of the housing over the overlap.

In the preferred mode of the invention, the tacking means and the welding means are implemented by a welding machine including welding heads which are rotatable around the overlap.

According to the eighth aspect of the invention, there is provided a gas sensor manufacturing machine designed to produce a as sensor using an assembly which has a length and includes (a) a housing which has a length made up of a first end portion, a second end portion, and a flange between the first and second end portions, (b) a cover which is made up of a small-diameter portion, a large-diameter portion, and a shoulder formed between the small-diameter portion and the large-diameter portion, and (c) an insulation porcelain disposed in the large-diameter portion of the cover in contact with the shoulder through an elastic member, (d) a cup-shaped sensor element disposed in the housing. The machine

comprises: (1) a first annular press plate fitted on the first end portion of the housing in engagement with the flange; (2) a second annular press plate fitted on the small-diameter portion of the cover in engagement with the shoulder of the cover; (3) a pressing means
5 for pressing the cover against the housing in a lengthwise direction of the assembly to fit an end of the large-diameter portion of the cover on the first end portion of the housing to form an overlap; (4) a tacking means for tacking the large-diameter portion of the cover to the first end portion of the housing at the overlap while pressing the
10 cover against the housing; (5) a rotating means for rotating the assembly, and (6) a welding means for welding the large-diameter portion of the cover to the first end portion of the housing over the overlap.

In the preferred mode of the invention, the tacking means
15 and the welding means are implemented by a welding machine including welding heads which are rotatable around the overlap.

BRIEF DESCRIPTION OF THE DRAWINGS

The present invention will be understood more fully from the detailed description given hereinbelow and from the accompanying
20 drawings of the preferred embodiments of the invention, which, however, should not be taken to limit the invention to the specific embodiments but are for the purpose of explanation and understanding only.

In the drawings:

25 Fig. 1 is a longitudinal sectional view which shows a

0960736-092404

shown a gas sensor 1 according to the first embodiment of the invention which may be employed in a burning control system or air-fuel ratio control system of an automotive vehicle to measure concentrations of components such as NO_x, CO, HC, and O₂ contained in exhaust gasses of the engine.

The gas sensor 1 generally includes a sensor element 2, a first insulation porcelain 12, a second insulation porcelain 11, a hollow cylindrical housing 19, and an air cover 10. The sensor element 2 is made of a laminated plate consisting of a solid electrolyte body, ceramic layers, and electrode layers. For example, U.S.P. No. 5,573,650, issued on November 12, 1996 to Fukaya et al. teaches a typical laminated sensor element, disclosure of which is incorporated herein by reference. The second insulation porcelain 11 is made of a hollow cylindrical member and is fitted within the housing 19 and holds therein the sensor element 2. The first insulation porcelain 12 is mounted on the second insulation porcelain 11 in alignment with each other and surrounds a base portion of the sensor element 2.

The housing 19 has a large-diameter portion or flange 190. The air cover 10 is fitted at an end thereof on a small-diameter portion (also referred to as a base end portion below) of the housing 19 to cover the first insulation porcelain 12. The gas sensor 1 also includes a protective cover assembly 191 consisting of an outer cover and an inner cover. The protective cover assembly 191 is installed on a head of the housing 19 to define a gas chamber into which a gas to be measured is admitted through gas holes 150

formed in the outer and inner covers.

The air cover 10 is made up of a large-diameter portion 105 greater in diameter than the first insulation porcelain 12, a small-diameter portion 106 smaller in diameter than the first insulation porcelain 12 and a shoulder 102 between the large-diameter portion 105 and the small-diameter portion 106.

The first insulation porcelain 12 is made of a hollow cylindrical insulating member and retained between an upper end, as viewed in Fig. 1, of the second insulation porcelain 11 and the shoulder 102 of the air cover 10. Between an inner wall of the shoulder 102 and a base end 129 of the first insulation porcelain 12, an annular elastic ring 13 made of a conical spring is disposed to urge the first insulation porcelain 12 into firm engagement with the second insulation porcelain 11, thereby establishing a hermetic seal in a gap between the second insulation porcelain 11 and the housing 19.

The assembling of the gas sensor 1 will be described below in brief.

First, an assembly 100 having a given length made up of the air cover 10, the elastic ring 13, the first insulation porcelain 12, the sensor element 2, the second insulation porcelain 11, the housing 19, and the protective cover assembly 191 is, as shown in Fig. 4, prepared. The fabrication of the assembly 100 will be described later in detail.

A manufacturing machine used in producing the gas sensor 1 includes an annular head plate 31, an annular base plate 32

above, mounted on the base end portion of the housing 19. An outer air cover 181 is provided around the air cover 10 and staked or crimped to retain a water-repellent filter 182 on the small-diameter portion 106 of the air cover 10.

5 The second insulation porcelain 11 is retained within the housing 19 hermetically through a metallic packing ring 192 placed on an annular tapered shoulder formed on an inner wall of the housing 19 and holds therein the sensor element 2 through a glass sealing member 193.

10 The first insulation porcelain 12 is, as described above, mounted directly on the base end 119 of the second insulation porcelain 11 and surrounded by the air cover 10. The elastic ring 13 is disposed between the shoulder 102 and the annular base end 129 of the first insulation porcelain 12 to elastically urge the first
15 insulation porcelain 12 into constant engagement with the second insulation porcelain 11. The annular base end 129 of the first insulation porcelain 12 is formed around a cylindrical projecting part or boss 128 on the end wall of the hollow cylindrical body 127. The elastic ring 13 is, as described above, made of a conical spring
20 and placed on the base end 129 of the first insulation porcelain 12 with the periphery thereof, as clearly shown in Fig. 4, oriented upward before the first insulation porcelain 12 is inserted into the air cover 10 in the assembling process.

 The first insulation porcelain 12 has disposed therein two
25 pairs of leads 211 and 212 (only two are shown for the simplicity of illustration) each of which is made of a metal wire folded elastically

09960736-092401
104260-9520960

to make an electric contact at one end with an electrode terminal (not shown) formed on the sensor element 2. The leads 211 and 212 extend at the other end through holes formed in the boss 128 of the first insulation porcelain 12 and connect with four leads 180 through connectors 184, respectively, for transmission of sensor signals between the sensor element 2 and an external device and supply of electric power to a heater installed on the sensor element 2.

The first insulation porcelain 12 has four vertical ribs 125 formed on an inner wall thereof at regular intervals. Between adjacent two of the vertical ribs 125, each of the leads 211 and 212 is retained and insulated from the adjacent ones.

The assembling of the gas sensor 1 will be described bellow in detail.

First, the assembly 100 is prepared in the following steps.

The sensor element 2 is, as clearly shown in Fig. 2, inserted into the second insulation porcelain 11. The glass sealing member 193 is fitted in the chamber of the second insulation porcelain 11 to establish a hermetic seal between the sensor element 2 and the second insulation porcelain 11. The glass sealing member 193 also serves to retain the sensor element 2 within the second insulation porcelain 11 rigidly.

The leads 211 and 212 connecting with the leads 180 through the connectors 184 are installed in the first insulation porcelain 12. The base portion of the sensor element 2 is inserted into the first insulation porcelain 12 to establish an electric

connection the electrodes formed on the sensor element 2 with the leads 211 and 212. The leads 211 and 212 are, as described above, made of a spring member and thus hold the base portion of the sensor element 2 elastically within the first insulation porcelain 12.

5 Next, the protective cover assembly 191 is, as clearly shown in Fig. 3, installed in the end of the housing 19 by staking. The metallic packing ring 192 is placed on the inner shoulder of the housing 19. The elastic ring 13 is put in the air cover 10. The air cover 10 is then put on the first insulation porcelain 12 and moved
10 downward, as indicated by an arrow in Fig. 3, without compressing the metal packing ring 192 tightly, thereby inserting the second insulation porcelain 11 into the housing 19 to complete the assembly 100. In the assembly 100, the metal packing ring 192 does not yet establish a hermetic seal between the second insulation
15 porcelain 11 and the housing 19. The elastic ring 13 is not pressed sufficiently to exert the elastic pressure on the base end 129 of the first insulation porcelain 12. Specifically, the elastic ring 13 is, as can be seen in Fig. 3, oriented at the periphery thereof upward.

 After the assembly 100 is prepared, the annular head plate
20 31 is, as described above in Fig. 4, fitted on the head of the housing 19 into contact with an end wall 195 of the flange 190 and then retained firmly in the manufacturing machine. Next, the annular base plate 32 is fitted on the small-diameter portion 106 of the air cover 10 and moved downward, as viewed in Fig. 4, by the press
25 mechanism 400 at a given high speed into contact with the shoulder 102.

After hitting on the shoulder 102 of the air cover 10, the annular base plate 32 is moved at a decreased speed and pushed downward to exert the pressure 39 on the shoulder 102 of the air cover 10 until the pressure 39 reaches about 650kg. This causes the base end portion of the housing 19 to be forced into the end of the air cover 10, thereby forming the overlap 15 and the elastic ring 13 to be flattened, thereby exerting the elastic pressure on the first insulation porcelain 12 downward in a longitudinal direction of the assembly 100. The metal packing ring 192 is also compressed to hermetically seal a gap between the second insulation porcelain 11 (i.e., the sensor element 2) and the housing 19. It is advisable that the pressure 39 be 1.2 times greater than the elastic pressure produced by the elastic ring 13 in order to force the housing 19 into the open end of the housing 19 reliably and to compress the metal packing ring 192 through the first insulation porcelain 11 for increasing the adhesion of the metal packing ring 192 to the surfaces of the first insulation porcelain 11 and the housing 19 to form a hermetic seal between the first insulation porcelain 11 and the housing 19 and lower than 7.8kN in order to avoid the breakage of the first and second insulation porcelain 11 and 12.

The assembly 100 is held under a pressure of 650kg.

Two welding heads 4, as shown in Fig. 5, are placed around the overlap 15 of the air cover 10 and the housing 19 and opposed diametrically to each other. Next, the welding heads 4 are turned together in a direction, as indicated by an arrow A, by an electric motor 600 to make two tack welds or joints 150 in the overlap 15.

5

10

15

20

25

Finally, the outer air cover 182 is fitted on the small-diameter

portion 106 of the air cover 10 through the water-repellent filter 182 and pressed or crimped radially to join the outer air cover 182 to the air cover 10 firmly.

As described above, the air cover 10 and the housing 19 are
5 tacked at the overlap 15, after which they are welded over the
periphery of the overlap 15 to join the air cover 10 to the housing 19
completely. The tack welding serves to secure a desired positional
relation between the air cover 10 and the housing 19, thus avoiding
any shift between the air cover 10 and the housing 19 in the
10 circumferential direction.

The tack welding is performed while the pressure is being
exerted on the assembly 100 through the annular head and base
plates 31 and 32, thus causing the elastic ring 13 to be flattened and
held between the shoulder 102 of the air cover 20 and the base end
15 129 of the first insulation porcelain 12, which results production of
pressure great enough to deform the metal packing ring 192 for
sealing the gap between the outer wall of the second insulation
porcelain 11 and the inner wall of the housing 19 hermetically.

The second embodiment will be described below which joins
20 the air cover 10 and the housing 19 without making the tack welds.

The assembly 100 is prepared in the same manner as in the
first embodiment. The annular head plate 31 is fitted on the head
of the housing 19 into contact with the end wall 195 of the flange
190 and then retained firmly in the manufacturing machine. Next,
25 the annular base plate 32 is fitted on the small-diameter portion 106
of the air cover 10 and moved downward, as viewed in Fig. 4, at a

0960736-092404

given high speed into contact with the shoulder 102.

After hitting on the shoulder 102 of the air cover 10, the annular base plate 32 is moved at a decreased speed and pushed downward to exert the pressure 39 on the shoulder 102 of the air
5 cover 10 until the pressure 39 reaches about 650kg. This causes the base end portion of the housing 19 to be forced into the end of the air cover 10, thereby forming the overlap 15 and the elastic ring 13 to be flattened, thereby exerting the elastic pressure on the first insulation porcelain 12 downward in a longitudinal direction of the
10 assembly 100. The metal packing ring 192 is also compressed to hermetically seal a gap between the second insulation porcelain 11 (i.e., the sensor element 2) and the housing 19.

The assembly 100 is held under a pressure of 650kg. The assembly 100 is turned up to a constant speed of 1500mm/minute.
15 The welding heads 4, as shown in Fig. 5, are placed around the overlap 15 of the air cover 10 and the housing 19 and opposed diametrically to each other. Laser beams are radiated from the welding heads 4 held stationary to weld the air over 10 to the housing 19 over the periphery of the overlap 15 of the rotating
20 assembly 100.

After the air cover 10 and the housing 19 are joined by the laser welding, the rotation of the assembly 100 is stopped. The annular base plate 32 is removed from the shoulder 102 of the air cover 10. The assembly 100 is removed from the annular head
25 plate 21.

Finally, the outer air cover 182 is fitted on the small-diameter

portion 106 of the air cover 10 through the water-repellent filter 182 and pressed or crimped radially to join the outer air cover 182 to the air cover 10 firmly.

The third embodiment will be described below which turns
5 the welding heads 4 to join the air cover 10 and the housing 19 without making the tack welds.

The assembly 100 is prepared in the same manner as in the first embodiment. The annular head plate 31 is fitted on the head of the housing 19 into contact with the end wall 195 of the flange
10 190 and then retained firmly in the manufacturing machine. Next, the annular base plate 32 is fitted on the small-diameter portion 106 of the air cover 10 and moved downward, as viewed in Fig. 4, at a given high speed into contact with the shoulder 102.

After hitting on the shoulder 102 of the air cover 10, the
15 annular base plate 32 is moved at a decreased speed and pushed downward to exert the pressure 39 on the shoulder 102 of the air cover 10 until the pressure 39 reaches about 650kg. This causes the base end portion of the housing 19 to be forced into the end of the air cover 10, thereby forming the overlap 15 and the elastic ring
20 13 to be flattened, thereby exerting the elastic pressure on the first insulation porcelain 12 downward in a longitudinal direction of the assembly 100. The metal packing ring 192 is also compressed to hermetically seal a gap between the second insulation porcelain 11 (i.e., the sensor element 2) and the housing 19.

25 The assembly 100 is held under a pressure of 650kg. The welding heads 4, as shown in Fig. 5, are placed around the overlap

15 of the air cover 10 and the housing 19 and opposed diametrically to each other. The welding heads 4 are turned at a given speed. Laser beams are then radiated from the welding heads 4 to weld the air over 10 to the housing 19 over the periphery of the overlap 15 of the assembly 100 held stationary.

After the air cover 10 and the housing 19 are joined by the laser welding, the welding heads 4 are stopped from rotating. The annular base plate 32 is removed from the shoulder 102 of the air cover 10. The assembly 100 is removed from the annular head plate 21.

Finally, the outer air cover 182 is fitted on the small-diameter portion 106 of the air cover 10 through the water-repellent filter 182 and pressed or crimped radially to join the outer air cover 182 to the air cover 10 firmly.

Since the assembly 100 is held stationary, the pressure exerted on the assembly 100 is kept constant, thereby keeping the elastic ring 13 flat during the welding of the air cover 10 to the housing 19, which establishes a firm seal between the second insulation porcelain 11 and the housing 19.

Fig. 6 shows a gas sensor 1 equipped with a cup-shaped sensor element 3.

The sensor element 3 consists of a cup-shaped solid electrolyte body 30 and a bar-shaped heater 35. The solid electrolyte body 30 is retained in a hollow cylindrical housing 19. The heater 35 is disposed within the solid electrolyte body 30. The housing 19, like the first embodiment, has the flange 190.

The sensor element 3 and the housing 19 are hermetically sealed by the packing ring 192 placed on an annular shoulder formed on an inner wall of the housing 19.

The solid electrolyte body 30 has a measuring electrode
5 formed on an outer wall thereof and a reference gas electrode formed on an inner wall thereof. The gas measuring electrode and the reference gas electrode are known, for example, in European Patent Application EP 0918215 A2 assigned to the same assignee as that of this application, disclosure of which is incorporated herein by
10 reference.

The first insulation porcelain 12 has formed therein, as clearly shown in Fig. 7, a cylindrical bore in which four grooves are formed radially at regular intervals. The first insulation porcelain 12 is placed at a lower end thereof, as viewed in Fig. 6, on an upper
15 end, as indicated by hatched lines S in Fig. 7, of the solid electrolyte body 30. Within spaces 227 defined between the grooves and the outer wall of the first insulation porcelain 12, metal terminal plates 213 and 214 are disposed which connect the measuring and reference gas electrodes of the sensor element 3 and the connectors
20 189. Other arrangements are identical with those in the one shown in Fig. 1, and explanation thereof in detail will be omitted here.

The assembling of the gas sensor 1 is accomplished in the following steps.

First, the protective cover assembly 191 is fitted at an end
25 thereof in an annular groove formed in the end of the housing 19 and fixed by staking a peripheral wall extension formed around the

groove. The peripheral wall extension is then welded to the end of the protective cover assembly 191. The heater 35 is fitted in the solid electrolyte body 30 of the sensor element 3. The metal terminal plates 213 and 214 are installed on the solid electrolyte
5 body 30.

Next, the sensor element 3 is built in the first insulation porcelain 12. The leads 180 are coupled with the metal terminal plates 213 and 214 through the connectors 189. The elastic ring 13 is placed on the first insulation porcelain 12. The air cover 10 is
10 fitted on the first insulation porcelain 12.

The metallic packing ring 192 is, as clearly shown in Fig. 8, put in the housing 19 and placed on the annular shoulder 300 formed on the inner wall of the housing 19. The air cover 10 is fitted on the first insulation porcelain 12 to form the assembly 100,
15 as shown in Fig. 9.

After the assembly 100 is prepared, the annular head plate 31 is, as shown in Fig. 9 , fitted on the head of the housing 19 into contact with an end wall 195 of the flange 190 and then retained firmly in the manufacturing machine. Next, the annular base plate
20 32 is fitted on the small-diameter portion 106 of the air cover 10 and moved downward to fit the end of the air cover 10 on the base end portion of the housing 19.

Next, the end of the air cover 10 is welded to the base end portion of the housing 19 in the same manner as one of the above
25 described first to third embodiment.

Other assembling steps are identical with those in the first

embodiment, and explanation thereof in detail will be omitted here.

While the present invention has been disclosed in terms of the preferred embodiments in order to facilitate better understanding thereof, it should be appreciated that the invention
5 can be embodied in various ways without departing from the principle of the invention. Therefore, the invention should be understood to include all possible embodiments and modifications to the shown embodiments which can be embodied without departing from the principle of the invention as set forth in the
10 appended claims.
